

## --Story OF Project--

# Amazon Sales Dashboard – Project Presentation

**"I developed this Amazon Sales Dashboard to help business stakeholders monitor sales performance, identify high-performing products, and make data-driven decisions. The objective was to convert raw sales data into meaningful business insights using Microsoft Excel."**

The project began with a raw sales dataset containing thousands of transaction records. The data included information such as product names, cities, states, units sold, sales amount, dates, and sales representatives.

My first responsibility was to clean the data by checking for duplicate records, missing values, formatting inconsistencies, and incorrect data types. After preparing the dataset, I created Pivot Tables to summarize the information and generated different KPIs that management could understand at a glance.

I designed the dashboard around the key business questions:

- How much total revenue has the company generated?
- How many units have been sold?
- Which products are selling the most?
- Which cities contribute the highest sales?
- Which states generate maximum revenue?

To answer these questions, I built several visualizations.

The first section contains **three KPI cards**, showing:

- Total Sales of **₹10.22 Million**
- Total Units Sold of **33,874**
- Sales distributed across **23 cities**

These KPIs provide executives with an instant overview of business performance.

Next, I created a **Product-wise Units Sold chart**, which immediately highlights the highest-selling products. From the analysis, **Nestle Smarties Pop-Up** emerged as the best-selling product with over **5,200 units sold**, followed by Nestle Fab and Nestle Aero Mint Potz. This information helps inventory and procurement teams maintain stock levels for high-demand products.

I then developed a **City-wise Sales Trend** chart. This visualization showed that sales were not evenly distributed across all cities. Some cities generated significantly higher revenue than others. These insights can help management decide where to increase marketing investments, expand operations, or improve customer engagement.

To provide a regional perspective, I created a **State-wise Sales Map**. The map quickly identifies states with the highest revenue contribution. Instead of reading long tables, decision-makers can immediately recognize geographical sales patterns and focus their business strategies accordingly.

From this dashboard, I derived several business insights:

- The company generated over **₹10 million** in revenue.
- More than **33,000 units** were sold.
- A few products contributed a significant portion of total sales.
- Some cities consistently outperformed others, indicating strong customer demand.
- Regional analysis revealed opportunities for expansion in underperforming states.

Technically, this project strengthened my skills in:

- Data Cleaning
- Excel Functions
- Pivot Tables
- Pivot Charts
- Dashboard Design
- KPI Reporting
- Business Analytics
- Data Visualization

The biggest learning from this project was understanding that **data itself doesn't create value—insights do**. A dashboard should not only display numbers but also help management make faster and better business decisions.

Overall, this project improved both my technical Excel skills and my ability to think from a business perspective.
